**ABSTRACT**

The Gnilna River was stocked with sea trout alevins. Their density attained locally 150/m<sup>2</sup>. Densities and length of one and two years old parr varied between years and sites. Density of one year old depended on initial density of alevins but very high mortality didn't. There were some relationships between lengths of both age groups and their densities and locality of sites. Some 1+ male parr were matured in fall. They were longer than 1+ parr in average.
